

# A Note on the Axioms for a Length Function on a Group

MOHAMMAD I. KHANFAR\*

*Mathematics Department, Yarmouk University, Irbid, Jordan.*

**ABSTRACT.** The author introduces the concept of a length function on a group satisfying only two axioms. Under such general length function, he investigates properties of the elements of the group. General results are obtained and a subgroup theorem is proved.

## 1. Introduction

The ideas of Nielsen<sup>[1]</sup>, and in particular the idea of calculating the extent of cancellation in a product of reduced words in a free group, had motivated Lyndon<sup>[2]</sup> to develop a set of axioms for a length function from a group to the set non-negative integers. He postulated six axioms for integer – valued length functions on free groups and free products.

In this paper we define a general length function; a real-valued length function satisfying only two of Lyndon's axioms, and then obtain some consequences and results under such a length function.

## 2. Length Functions

We give the following definition:

### 2.1 Definition

Let  $G$  be a group. A length function  $|| : G \rightarrow \mathbb{R}$  is a function assigning to each element  $x$  in  $G$  a real number  $|x|$  such that for all  $x, y, z$  in  $G$  the following axioms are satisfied:

---

\**Present Address:* Mathematics Department, Faculty of Science, K.A.U., Jeddah, Saudi Arabia.

$$A_2. \quad |x^{-1}| = |x|$$

$$A_4. \quad d(x,y) < d(x,z) \text{ implies } d(x,y) = d(y,z)$$

$$\text{where } d(x,y) = \frac{1}{2} [|x| + |y| - |xy^{-1}|].$$

That is, the two smallest numbers in the triple of real numbers  $d(x,y)$ ,  $d(x,z)$ ,  $d(y,z)$  are equal. The numbering of the axioms is due to Lyndon<sup>[2]</sup>.

An example of a length function is the usual modulus function on  $\mathbb{R}$ , the additive group of the real numbers.

## 2.2 Proposition

For  $x, y \in G$ , we have

$$(i) \quad d(x,y) \geq \frac{1}{2} |1|, \quad 1 \text{ is the identity element of } G$$

$$(ii) \quad |x| \geq |1|$$

$$(iii) \quad d(x,y) \leq |x| - \frac{1}{2} |1|.$$

### Proof

$$(i) \quad 2d(x,1) = |x| + |1| - |x| = |1| = 2d(1,y); \text{ hence by } A_4, \quad 2d(x,y) \geq |1|.$$

$$(ii) \quad 2d(x,x) = |x| + |x| - |1| \geq |1|, \text{ by (i).}$$

$$\begin{aligned} (iii) \quad 2d(x,y) &= |x| + |y| - |xy^{-1}| \\ &= 2|x| - (|x| + |xy^{-1}| - |y|) \\ &= 2|x| - 2d(yx^{-1}, x^{-1}) \\ &\leq 2|x| - |1| \end{aligned}$$

$$\text{That is, } d(x,y) \leq |x| - \frac{1}{2} |1|.$$

As another example, let any element  $x = x_1 x_2 \dots x_n$  as a reduced word in a free group  $F$  with basis  $X$ . Then  $|x| = n$  defines a length function on  $F$  satisfying the above axioms.

If the length function is normalized by subtracting  $|1|$ , then it still satisfies  $A_2$  and  $A_4$ ; so without loss of generality, we may assume that the length function on  $G$  satisfies axiom:

$$A'_1. \quad |1| = 0$$

This is a weakened form of Lyndon's axiom:

$$A_1. \quad |x| = 0 \text{ if and only } x = 1 \text{ in } G;$$

but it may be noted here that  $A'_1$  is added more for convenience than necessity.

Using Proposition 2.2 and  $A'_1, A_2, A_4$  the consequences in the following Proposition are immediately obtained.

### 2.3 Proposition

- (i)  $d(x,y) \geq 0$  ; this is Lyndon's axiom  $A_3$
- (ii)  $d(x,x) = |x| \geq 0$
- (iii)  $d(x,y) \leq |x|$
- (iv)  $d(x,y) = d(y,x)$ .

## 3. Non-Archimedean Elements

### 3.1 Definition

In a group  $G$  with a length function an element  $x$  is archimedean if  $|x^2| > |x|$  and non-archimedean if  $|x^2| \leq |x|$ .

Let  $N = \{ x \in G : |x^2| \leq |x| \}$ .

### 3.1 Proposition

Let  $x$  be an element of  $G$ . Then

- (i)  $x \in N$  implies  $|x^n| \leq |x|$  for all integers  $n \geq 0$ ,
- (ii)  $x \notin N$  implies  $|x^n| = |x| + (n - 1)t$  for any positive integer  $n$  and where  $t = |x^2| - |x|$ .

### Proof

(i) Let  $x \in N$ . We use induction on  $n$ . Result holds trivially for  $n = 0, 1$  and by definition for  $n = 2$ .

Suppose result is true for all non-negative integers  $\leq n$ .

That is,  $|x^{n-1}|, |x^n| \leq |x|$ .

Now  $2d(x^n, x) = |x^n| + |x| - |x^{n-1}| \geq |x^n|$ ,

$$2d(x, x^{-1}) = |x| + |x^{-1}| - |x^2| \geq |x| \geq |x^n|;$$

hence by  $A_4$ ,  $2d(x^n, x^{-1}) \geq |x^n|$ .

That is,  $|x^n| + |x| - |x^{n+1}| \geq |x^n|$ , giving  $|x^{n+1}| \leq |x|$ .

Hence result holds for all integers  $n \geq 0$ .

(ii) For  $x \notin N$ , the formula  $|x^n| = |x| + (n - 1)t$  holds for  $n = 1, 2$ . Assume result for all positive integers  $\leq n$ .

That is,  $|x^{n-1}| = |x| + (n - 2)t$ ,  $|x^n| = |x| + (n - 1)t$ .

We have,  $2d(x^n, x) = |x^n| + |x| - |x^{n-1}| = |x| + t$ ,

$$2d(x, x^{-1}) = |x| + |x| - |x^2| = |x| - t.$$

For  $x \notin N$ ,  $t > 0$  and therefore  $|x| - t < |x| + t$ .

Thus  $2d(x, x^{-1}) < 2d(x^n, x)$ , and hence by  $A_4$ ,

We have  $2d(x^n, x^{-1}) = 2d(x, x^{-1})$ .

That is,  $|x^n| + |x| - |x^{n+1}| = |x| - t$ ,

hence  $|x^{n+1}| = |x^n| + t = |x| + nt$ .

Hence results holds for all positive integers  $n$ .

The Proposition implies that an element  $x$  of finite order  $G$  is non-archimedean, and if  $x$  is archimedean then the lengths  $|x^n|$  are unbounded, a result obtained in<sup>[2]</sup>.

### 3.1.1 Corollary

$x \in N$  implies  $yx^{-1} \in N$  for all  $y \in G$ .

#### Proof

$$2d(yx^n, y) = |yx^n| + |y| - |yx^{n+1}| \quad (1)$$

$$2d(y, x^{-n}) = |y| + |x^n| + |yx^n| \quad (2)$$

From (1) and (2) respectively, we have

$$|yx^n y^{-1}| \leq |yx^n| + |y| \text{ and } |yx^n| \leq |y| + |x^n|.$$

By part (i) of the Proposition,  $|x^n| \leq |x|$  for all  $n \geq 0$ .

Therefore,  $|yx^n y^{-1}| \leq |x| + 2|y|$ .

That is, the lengths  $|(yx^{-1})^n|$  are bounded and hence  $y x y^{-1} \in N$ .

### 3.2 Proposition

$K = \{ x \in G : |x| = 0 \}$  is a subgroup contained in  $N$ .

#### Proof

Clearly  $K$  is contained in  $N$ .  $K$  is a subgroup since if  $|x| = |y| = 0$  then  $-1/2 |xy^{-1}| = d(x, y) \geq 0$ ;

therefore,  $|xy^{-1}| = 0$ .

### 3.2 Definition

A relation  $\sim$  on  $G$  is defined by  $x \sim y$  if and only if  $|xy^{-1}| \leq |x| = |y|$  or equivalently by  $x \sim y$  if and only if  $2d(x, y) \geq |x| = |y|$ .

This is an equivalence relation on  $G$ ; it is clearly reflexive and symmetric and transitivity follows from  $A_4$ .

Let  $C(x)$  denote the equivalence class of  $x \in N$ , and  $M(x) = \{ yz : y, z \in C(x) \}$ .

### 3.3 Proposition

$x \sim x^{-1} \sim y \sim y^{-1}$  implies that  $xy \in N$

#### Proof

For any element  $x$  of  $G$ ,  $x \sim x^{-1}$  if and only if  $x \in N$ .

As the elements  $x, x^{-1}, y, y^{-1}$  are all equivalent, we have

$$|xy^{-1}|, |xy|, |yx| \leq |x| = |x^{-1}| = |y| = |y^{-1}|.$$

$$2d(xy, y) = |xy| + |y| - |x| = |xy|,$$

$$2d(y, x^{-1}) = |y| + |x| - |yx| = 2|x| - |yx|,$$

$$2d(xy, x^{-1}) = |xy| + |x| - |xyx|.$$

Since  $|xy|, |yx| \leq |x|$  it follows that  $d(xy, y) \leq d(y, x^{-1})$ , and hence by  $A_4$ ,  $d(xy, y) \leq d(xy, x^{-1})$ , giving  $|xyz| \leq |x|$ .

$$\text{Now } 2d(xy, y^{-1}x^{-1}) = |xy| + |xy| - |(xy)^2|,$$

$$2d(y^{-1}x^{-1}, x^{-1}) = |xy| + |x| - |y| = |xy|,$$

$$2nd(xy, x^{-1}) = |xy| + |x| - |xyx|.$$

As  $|xyx| \leq |x|$  it follows that  $d(y^{-1}x^{-1}, x^{-1}) \leq d(xy, x^{-1})$  and hence by  $A_4$ ,  $d(y^{-1}x^{-1}, x^{-1}) \leq d(xy, y^{-1}x^{-1})$  giving  $|(xy)^2| \leq |xy|$ . Thus  $xy \in N$ .

### 3.1 Theorem

$H = C(x) \cup M(x)$  is a subgroup of  $G$ .

#### Proof

By definition  $C(x)$  is a subset of  $N$  and, by Proposition 3.3  $M(x)$  is also contained in  $N$ ; therefore  $H$  is contained in  $N$ . Since  $C(x)$  contains the inverses of its elements, the same is true for  $M(x)$ , which contains the identity element 1. Thus it remains to show that  $H$  is closed under multiplication. For this purpose we consider products of elements in  $C(x)$ . Let  $x, y, z \in C(x)$ , then if  $|xy| = |x| = |y|$  it follows from definition 3.2 that  $xy \sim y$  and hence  $xy \sim C(x)$ , and so  $xyz \in M(x)$ . If  $|xy| < |x| = |y| = |z|$  then  $2d(xy, y) < 2d(y, x^{-1})$ , and  $A_4$  implies  $d(xy, y) = d(xy, x^{-1})$ , giving  $|xyx| = |x|$ ; and we consider

$$2d(xy, x) = |xyx| + |x| - |xy| = 2|x| - |xy|,$$

$$2d(z^{-1}x, x) = |z^{-1}x| + |x| - |z^{-1}| = |z^{-1}x|.$$

Since  $x \sim x^{-1} \sim z \sim z^{-1}$ , we have  $|z^{-1}x| \leq |z^{-1}| = |x^{-1}| = |x|$ .

Hence  $d(z^{-1}x, x) < d(xy, x)$  and  $A_4$  implies that  $d(z^{-1}x, x) = d(xy, z^{-1}x)$ , giving  $|xyz| = |x|$ .

Thus  $|xy| = |xyzz^{-1}| < |xyz| = |x| = |z|$ . By definition 3.2, this shows that  $xyz \sim z \sim$

$x$  and  $xyz \in C(x)$ . Also, if  $x, y, z, w \in C(x)$  then, if  $|xy| = |x| = |y|$ , we have shown above that  $xy \in C(x)$ , and so  $xyzw$  is the product of three elements from  $C(x)$  which, as we have shown is an element of  $C(x) \cup M(x)$ . If  $|xy| < |x| = |y|$ , then we have shown that  $xyz \in C(x)$ , and so  $xyzw \in M(x)$ . These cases cover the product of two elements of  $H = C(x) \cup M(x)$ , proving that  $H$  is a group.
